

Designation: F1374 – 92 (Reapproved 2020)

Standard Test Method for Ionic/Organic Extractables of Internal Surfaces-IC/GC/FTIR for Gas Distribution System Components¹

This standard is issued under the fixed designation F1374; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

Semiconductor clean rooms are serviced by high-purity gas distribution systems. This test method presents a procedure that may be applied for the evaluation of one or more components considered for use in such systems.

1. Scope

1.1 This test method establishes a procedure for testing components used in ultra-high-purity gas distribution systems for ionic and organic surface residues.

1.2 This test method applies to in-line components containing electronics grade materials in the gaseous form.

1.3 Limitations:

1.3.1 This test method is limited by the sensitivity of the detection instruments and by the available levels of purity in extracting solvents. While the ion and gas chromatographic methods are quantitative, the Fourier transform infrared spectroscopy (FTIR) method can be used as either a qualitative or a quantitative tool. In addition, the gas chromatography (GC) and FTIR methods are used to detect hydrocarbons and halogenated substances that remain as residues on component internal surfaces. This eliminates those materials with high vapor pressures, which are analyzed per the total hydrocarbons test, from this test method.

1.3.2 This test method is intended for use by operators who understand the use of the apparatus at a level equivalent to twelve months of experience.

1.4 The values stated in SI units are to be regarded as the standards. The inch-pound units given in parentheses are for information only.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and deter-*

mine the applicability of regulatory limitations prior to use. Specific hazard statements are given in Section 6.

1.6 *This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 *spool piece*—a null component, consisting of a straight piece of electropolished tubing and appropriate fittings, used in place of the test component to establish the baseline.

3.1.2 *standard conditions*—101.3 kPa, 0.0°C (14.73 psia, 32.0°F).

3.1.3 *test component*—any device being tested, such as a valve, regulator, or filter.

3.1.4 *test fluid blank*—a volume of test solvent adequate for analysis.

¹ This test method is under the jurisdiction of ASTM Committee F01 on Electronics and is the direct responsibility of Subcommittee F01.10 on Contamination Control.

Current edition published April 15, 2020. Published May 2020. Originally approved in 1992. Last previous edition approved in 2012 as F1374–92(2012). DOI: 10.1520/F1374-92R20.

identifies contaminants based on characteristic frequencies of absorption of infrared radiation. By identifying combinations of absorption frequencies, identification of contaminants can be made (see [Appendix X1](#)).

6. Hazards

6.1 It is required that the user have a working knowledge of the respective instrumentation and proper handling of test components for trace analysis. Good laboratory practices must also be followed.

6.2 Use safety precautions such as proper ventilation and disposal when handling solvents.

6.3 Gloves are to be worn at all times. After use, the gloves are to be rinsed in the appropriate test fluid.

NOTE 2—An alternative could be the use of disposable gloves, using a new glove for each test.

7. Calibration

7.1 Calibrate instruments using standard laboratory practices and manufacturer's recommendations.

8. Test Procedure

8.1 *Temperature*—The test component and the spool piece are to be tested at a constant temperature $\pm 2^{\circ}\text{C}$ in the range of 26°C (18 to 78°F). Solvents used must be at the same temperature.

8.2 Rinse the outside of the spool piece with the test fluid (DI water (ionic) or IPA (organic)) to be used for analysis. Rinse the caps and rinse any gaskets or ferrules to be used with the respective test fluid.

8.3 Remove the caps accompanying the spool piece. Install the stainless steel cap, rinsed as in [8.1](#), on one end of the spool piece. Using a buret or graduated pipet, measure the amount of test fluid required to completely fill the internal volume of the spool piece. Extreme care must be taken to avoid overfilling the spool piece. Overfilling invalidates the test. Cap the open end.

8.4 Invert the spool piece 20 times across the long axis, one inversion every 30 s. Allow the spool piece to rest along the horizontal axis for 24 h at a constant temperature $\pm 2^{\circ}\text{C}$ (see [8.1](#)).

NOTE 3—Since air is likely to be introduced when capping, the inversion insures uniformity of the fluid.

8.5 After 24 h, invert the spool piece 20 times across the long axis, one inversion every 30 s.

8.6 Remove one cap and sample the fluid. Recap the spool piece immediately to limit evaporation of the solvent. If multiple samples are to be run, agitate the spool piece (four inversions in accordance with [8.4](#)) prior to each sample.

8.7 If any species are detected, the spool piece is to be cleaned with the appropriate test fluid and analysis to be repeated until it is suitable for use as a control.

8.8 Repeat 8.2 – 8.6 simultaneously with the test component and the spool piece.

8.9 For the following components, observe the given guidelines.

8.9.1 *Regulators*—Wind the handle fully counter clockwise (or fully clockwise for a back pressure regulator). This will close the regulator. Fully fill the inlet side first with test fluid. Then cap the inlet end. Turn the regulator over and prepare to fill the outlet end. Prior to adding the test fluid, turn the handle in the reverse direction to open the regulator. Now fully fill the outlet end. Cap the outlet and begin the extraction. During extraction, the regulator must be resting on its side. Due to the small orifice separating the high and low pressure sides of a regulator, take samples from both the inlet and outlet.

8.9.2 *Valves*—Make sure that all valves are fully open before starting the test. If the minimum orifice is <20 % of the tube nominal diameter, take samples from both ends.

8.9.3 *Electropolished Tubing*—An entire random length (stick) of tubing must be used for this test. This is to ensure that the sample is representative of the entire tube. If it is not possible to invert the sample, it may be rolled.

8.9.4 *Filters*—With the outlet end capped, fully fill the inlet side with test fluid. Then cap the inlet end. Turn the filter over and fill the outlet end. During the filling operation, slightly tilt and gently shake the filter to release air bubbles that may be trapped in the filter structure. Cap the outlet and begin the extraction. During extraction, the filter must be resting on its side. Take samples from both the inlet and outlet.

8.10 Analyze as follows, using the appropriate method:

8.10.1 *IC*—Inject the water sample into the IC using the appropriate injection method. Use three injections for cations and three injections for anions. Record the identification and quantify by the appropriate mathematical method.

8.10.2 *GC*—Inject the IPA sample into the GC using the appropriate injection method. Use three injections. Record the

identification and quantify by appropriate mathematical method. Only analyze for those components resolved with retention times greater than the solvent IPA peak.

8.10.3 *FTIR*—Analyze the sample by the appropriate method to minimize solvent interference peaks (such as evaporation on a salt plate).

9. Report

9.1 Report the following information:

9.1.1 *IC*—Report the IC data as micrograms of ion per litre extract fluid, tabulated by ionic species (for example Na^+ , SO_4^{-2}). Also report the data as mass of each ionic species per test component in the same table, (see Fig. 1).

9.1.2 *GC*—Report the GC data as total mass of organics detected per litre extract fluid and total mass of organics per test component, (see Fig. 2).

9.1.3 *FTIR*—Report the FTIR data in tabular form, listing frequency of absorption band and organic specie with matching characteristic absorption bands. Analysis of the spectrum leading to identification of materials in the residue will also include reference spectra, (see Fig. 3).

9.2 Attach the spectra for reference. A proper subtraction of the fluid blank spectrum from the sample spectra is acceptable, provided that proper interpretation techniques are followed and the spool piece and fluid blank spectra are virtually identical.

10. Precision and Bias

10.1 Precision and bias for this test method are being determined.

11. Keywords

11.1 components; contamination; extraction; gas distribution components; ionic extractables; organic extractables; surface contamination

APPENDIX

(Nonmandatory Information)

X1. ALTERNATIVE TESTS

X1.1 *Liquid Chromatography/Mass Spectrometry (LC/MS)*—In addition to gas chromatography and Fourier transform infrared spectroscopy, these are quantitative or qualitative methods, or both, that allow resolution and identification of organic compounds.

X1.2 *Quadrupole Mass Spectrometer (QMS)*—The quadrupole mass spectrometer accurately detects hydrocarbon species by ionizing organic moieties in a vacuum. The ionized fragments are detected semi-quantitatively and individually.

X1.3 *Graphite Furnace Atomic Absorption Spectroscopy (GFAAS)*—This instrument quantitatively determines

the mass of species based on their absorption of specific wavelengths. An elemental lamp emits the specific radiation that is passed to a photodetector after being absorbed by the sample in the furnace. It is highly sensitive to cations but limited in scope for anions.

X1.4 *Inductively Coupled Plasma Atomic Emission Spectroscopy (ICP-AES)*— This instrument quantitatively determines the mass of the species based on the emission spectra of the sample placed in the plasma. It is highly sensitive to cations but limited in scope for anions.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.
